Vesco, LLC was originally founded as Vacuum Electric Switch Co. in 1996. Our company specializes in new and replacement vacuum switchgear, controls, and field services of existing Vesco and Joslyn HiVoltage (now owned by ABB ) and other electrical utility equipment.

As you will see in this catalog, Vesco manufactures a wide array of new vacuum switches, PLC and microprocessor-based controls for switching electric arc furnace transformers, capacitor banks, harmonic filter banks, reactors for steel making, electric utility, and renewable energy applications. Our vacuum switches and replacement parts incorporate many design enhancements and improved methods of manufacturing over the original product designs.

Additionally, Vesco can supply replacement parts which are suitably interchangeable for vacuum switches of the same ratings manufactured by Joslyn Hi-Voltage. Field services are also offered by Vesco, delivering a wide array of options from new product installation, on-site repairs, and upgrades for both existing switches and controls.

## Switches and Controls Description

Vesco manufactures a variety of switches and controls that can be used in a wide range of applications. There are many variations based on the application, the voltage and current ratings, the operating control voltage and other system requirement parameters.

Switches are configured in a single mechanism/three phase arrangement or in a single mechanism/single phase arrangement. Switches that are of the single mechanism/three
 phase style can be operated with an internal motor operated mechanism or an internal solenoid operated mechanism. Switches that are configured in a single mechanism/single phase arrangement, so one mechanism per phase, can only be operated with a solenoid mechanism.

## Motor Operated Mechanisms

Motor operated mechanisms have an expected operating life of about 30,000 operations. They can have simple, self-contained control systems with a control current demand of less than six amperes. Motor operated switches are configured with 15 or 35 pin connectors and have two each form A (normally open) and B (normally closed) or six each form A and B contacts respectively.

Motor operated switches are typically used for capacitor bank switching and sectionalizing but not for arc furnace switching applications. The motor mechanism cannot be used for single mechanism/single phase arrangements, since each phase needs to open and close near simultaneously, which is not possible with independent motor operators on three phase systems.

## Solenoid Operated Mechanisms

The solenoid operated mechanisms provide high speed operation and a long operating life and can typically achieve 100,000 operations and even up to 200,000 with minimal maintenance. The solenoid operated mechanism do require an external interface control with interposing relays because each solenoid requires a current in the range of 60 to 65 amperes peak for $11 / 2$ cycles. Therefore, it is very important that the power source and wiring are sized appropriately for the switch to operate properly and to recognize the expected long life.

If the proper power cannot be achieved, then controls with a stored energy option (Page 13) can be supplied that will reduce the power source and larger size wiring requirements. For existing installations with inadequate current supply, the Vesco Boost Box (Page 23) can be used between the existing switch and control.

## Controls

Vesco controls are designed for various applications including capacitor switching, electric arc furnace switching, distribution sectionalizing and more. These controls can take a variety of input voltages and can be set to precisely control the closing of the switches in applications where that is desirable, such as capacitor switching and arc furnace switching. Details can be found in the control section on Page 13

## Vacuum Switches

15kV, 600A Three Pole Switch

The common uses of this switch are for electrical distribution line sectionalizing and arc furnace or capacitor bank switching. This switch may have either a self-contained motor or solenoid operated mechanism. These two mechanisms differ in the complexity of the required control systems, control current demand, available operating voltages, mechanical life, and the precision of the timing of switch contact closing.

Solenoid operated switches are commonly used for capacitor switching and arc furnace switching. For special applications, two or more of these switches may be used along with three resistor modules to form a resistor insertion switch. The solenoid operated switch can be configured and operated with three modules connected in parallel. Each module's current rating is de-rated to 500A when connected in parallel for a total current of 1500A per phase. Three separate switches are then required to make a three-phase set. Solenoid operated switches have one form A (normally open) and one form B (normally closed) contact and is packaged with an external interface control that matches the option and application requirements.

Repair parts for this switch can be found beginning on Page 48.

| 3 POLE | $110-150$ | 15 | 600 | 35 PIN MOTOR | 125 VDC | 1001057 | 1003308 G 2 |

The common use of the 25 kV switch is for ungrounded capacitor switching. This switch may have either a motor or solenoid operated mechanism. These two mechanisms differ in the complexity of the required control systems, control current demand, available operating voltages, mechanical life, and the precision of the timing of switch contact closing.

The six vacuum interrupters on this switch require the power of double opening and closing solenoids. When installing a solenoid operated switch the voltage drop from the station power transformers or batteries must be considered for the switch to operate properly. The current of the two solenoids can be instantaneously as high as 120 amperes. Vesco control cables include 16 AWG wire, but some other manufacturers can have a lesser gauge wire. Even with 16 AWG wire there can be substantial voltage drop in a surprisingly short length of cable. The best way to compensate for this large voltage drop and eliminate any potential operating issues is to install a stored energy control shown on page 13.

Repair parts for this switch are found beginning on page 48.

34kV, 300A Three Pole Switch

The common uses of this 34 kV switch are capacitor switching, reactor switching, and distribution line sectionalizing. This switch may have either a motor or solenoid operated mechanism. These two mechanisms differ in the complexity of the required control systems, control current demand, available operating voltages, mechanical life, and the precision of the timing of switch contact closing.

The six vacuum interrupters on this switch require the power of double opening and closing solenoids. When installing a solenoid operated switch the voltage drop from the station power transformers or batteries must be considered for the switch to operate properly. The current of the two solenoids can be instantaneously as high as 120 amperes. Vesco control cables include 16 AWG wire, but some other manufacturers can have a lesser gauge wire. Even with 16 AWG wire there can be substantial voltage drop in a surprisingly short length of cable. The best way to compensate for this large voltage drop and eliminate any potential operating issues is to install a stored energy control shown on page 13.

Vesco offers this switch in three different versions - Standard Vacuum Interrupter Gap ( 0.160 inch ), Standard Vacuum Interrupter Gap ( 0.160 inch) with grading capacitors, and an extended Interrupter Vacuum Gap (0.320) with grading capacitors. Adding grading capacitors and using a larger vacuum interrupter gap can improve operating performance for capacitor switching applications by eliminating the negative impact of stray capacitance due to external components being in close proximity of the series connected vacuum interrupters in this configuration.

Various factors can cause unequal recovery voltage distribution over the two vacuum interrupters in series which are designed and configured to equally share the interrupting duty of the switching application. This is most likely to occur when the switch is used on poles where objects closer than 32 inches in proximity may cause a larger portion of the recovery voltage to appear across the upper module. This may cause the capacitor switching capability to be reduced. Grading capacitors tend to equalize the capacitance across each vacuum interrupter diminishing the effect of parasitic or stray capacitance. The recovery voltage withstand capability is further improved by increasing the contact open gap from 0.160 to 0.320 inches. The larger gap requires more energy than is available from a solenoid mechanism, so it is only possible with motor operated switches.

Switch repair parts are shown starting on page 48. Replacement modules for this 34 kV 300 A switch are available both with and without grading capacitors. Modules with and without grading capacitors cannot be installed on the same switch.

34kV, 600A Single Pole Switch

This switch is used for both capacitor and arc furnace switching. It is solenoid operated because it is used in three phase sets requiring near simultaneous contact closure. Based on its fast and consistent speed, it can close at zero voltage for capacitor switching or at peak voltage for arc furnace switching. Its solenoid operating current is 60 to 65 amperes peak for $11 / 2$ cycles. If the solenoid operating time exceeds $11 / 2$ cycles, generally the power being supplied to the system is not adequate to maintain reliable and proper operations and needs to be verified.

When this switch is used for capacitor switching and does not have 32 inches of free space surrounding it, the switch requires grading capacitors to assure proper operation. The grading capacitors assure that the recovery voltage is equally distributed over its two vacuum interrupters in series. Repair parts for this switch can be found starting on Page 48.

This switch can be operated from a variety of AC and DC sources and is best operated by selecting from the controls shown beginning on page 13 . This switch has one form A (normally open) and one form B (normally closed) auxiliary contact and is packaged with an external interface control that matches the option and application requirements.

Multiple switches in this configuration are used in parallel for arc furnaces with up to 4000A primary current. The switch current rating is de-rated to 500A when used in parallel. Arc furnace controls that can operate from one to six switches per phase are shown staring on page 26. An arc furnace transformer control can optionally be operated using either resistor insertion or peak voltage closing to reduce in-rush currents.

Accessories available for this switch include both current limiting reactors and resistor modules. The 30 microhenry reactor replaces the buss bar between the two modules. The reactor is used to limit in-rush currents when two capacitor banks are installed in parallel on a single buss. This switch also can be adapted as a resistor insertion switch by installing two 80 ohm resistor modules, one each, on top of the two vacuum interrupter modules. The two resistor modules are then series connected with the buss bar and have a total series resistance of 160 ohms. The controls required are shown starting on page 13. The reactors and resistors are shown on page 20.

This switch is principally used for arc furnace switching but also can be used for solidly grounded neutral capacitor switching applications. When the switch is used for capacitor switching and is not surrounded by 32 inches of free space, it must have grading capacitors to assure that the recovery voltage is equally distributed over the two vacuum interrupters in series.

The switch is solenoid operated because it is used in three phase sets requiring near simultaneous contact closure. Capacitor switching is limited to switching solidly grounded 46 kV systems having maximum currents of 200 amperes.

The switch can be used to switch an arc furnace at 46 kV with multiple switches of this configuration used in parallel for up to 4000A primary current capability. Switches connected in parallel are de-rated to 500A. This switch has one form A (normally open) and one form B (normally closed) auxiliary contact. Capacitor switching is best done with a stored energy control shown starting on page 13. An arc furnace control is shown on page 22. This switch's repair parts are shown beginning on page 48.

## 46kV \& 69kV, 300A Single Pole Switch

The 46 and 69 kV switches shown below are commonly used for capacitor bank switching in substations. They may also be used for switching induction furnaces and reactor banks. When the switch is used for capacitor switching and is not surrounded by 32 inches of free space, the switch must have grading capacitors to assure that the recovery voltage is equally distributed over the three or four vacuum interrupters in series. Otherwise, the switch's performance will be degraded.

This switch is used for both capacitor and arc furnace switching. It is solenoid operated because it is used in three phase sets requiring near simultaneous contact closure. Based on its fast and consistent speed, it can close at zero voltage for capacitor switching or at peak voltage for arc furnace switching. Its solenoid operating current is 60 to 65 amperes peak for $11 / 2$ cycles. If the solenoid operating time exceeds $11 / 2$ cycles, generally the power being supplied to the system is not adequate to maintain reliable and proper operations and needs to be verified.

This switch is used for both arc furnace and capacitor switching and is similar to the Joslyn ${ }^{\mathrm{TM}}$ VBU*. This switch was designed specifically for high duty applications such as capacitor switching and electric arc furnace switching. At 69 kV and above, this switch may be the only switch available with a practical operating life for switching arc furnaces with minimal maintenance.

Vesco manufactures new VES-U switches, replacement VBU vacuum modules and switch operating mechanisms as shown on page 15. Vesco offers both capacitor and an arc furnace switch controls for this switch.

The VES-U switch can be used to reduce overvoltage transient with zero voltage closing capability for capacitor banks or to reduce in-rush currents by peak voltage switching for arc furnace-applications. It can be used as a resistor insertion switch for arc furnaces as well.

## Vacuum Switches for Special Applications

15kV, 600A Two Pole Switch

This solenoid operated two pole switch has two applications. The first is to achieve 1000 amperes of current capacity at 15 kV by connecting the two modules in parallel with buss bars. In this configuration it is used for arc furnace switching. When the modules are connected in parallel, three separate switch mechanisms are required to make a three-phase set. Arc Furnace controls for this switch are shown starting on page 26. The second application is in conjunction with the transverse single pole switch shown below for switching ungrounded neutral capacitor banks at zero voltage. The control required for this application is found on page 13. Repair parts are the same as for a 15 kV three pole switch and are found starting on page 48.

## 15kV, 600A Single Pole Switch

Longitudinal

This single pole switch is used for zero voltage closing of capacitor banks to reduce in-rush currents and associated transient overvoltage conditions. It is available with two terminal pad orientations as shown above. With the terminal pads perpendicular to the length of the switch, it is used with the two-pole switch above to switch ungrounded neutral capacitor banks at zero voltage. The longitudinal form above is used in three phase sets to switch capacitor banks at zero voltage. These switches contain one form A (normally open) and one form B (normally closed) auxiliary contact. The required controls are shown on page 13. The repair parts are the same as for the three pole 15 kV switch and are found beginning on page 48 .

## 34kV, 600A Three Pole Sectionalized

This switch is used for 34 kV distribution line sectionalizing on solidly grounded systems only. The switch utilizes the self-contained motor operator because it is used as a sectionalizing switch in remote locations where a limited current supply is available, and a simple control is an advantage. The operating current is only 6 amperes for this switching configuration. Switches with 15 or 35 pin connectors have two each form A (normally open) and form B (normally closed) or six each form A and form B contacts respectively.

## 34kV, 600A Single Pole Switch - Extended Creep

This switch is a 34 kV switch is supplied with 350 kV BIL line-to-ground insulators commonly used on 69 kV systems. The extra creepage is useful where atmospheric contamination is a problem. This switch is also used to short insertion resistors on an arc furnace having a 69 kV primary voltage. This switch contains one form A (normally open) and one form B (normally closed) auxiliary contact. A control for operating this switch is shown on page 24. The repair parts except for the pull rods and the line-to-ground insulators are the same as for the 34 kV switch shown starting on page 48 .

The above switch is solenoid operated for use in special applications such as in laboratory or electrical test needs where versatility is an advantage. The switch can be either a 34 kV 600 A or a 15 kV 1000 A switch by removing or installing the lower buss bar respectively. The double solenoid version of this switch has twice as many solenoids to increase the speed of contact closure. This switch contains one form A (normally open) and one form B (normally closed) auxiliary contact. The controls for these switches are shown on page 13. The repair parts except for the modules are the same as for the 34 kV switch shown on page 48 .

## Harmonic Filter Switch

Left Hand Configuration

This 34 kV switch is for switching harmonic filters up to and including the 12th. harmonic. This switch configuration is also ideal standardization for windfarm applications where there is a potential for higher-than-normal harmonic content that could negatively impact performance on traditional rated and configured switches. Unlike the other switches of a similar design, the modules on the Vesco harmonic filter switch contain grading capacitors to assure even distribution of the recovery voltage over the three modules. Modules with and without grading capacitors cannot be combined on the same switch and are special for this switch. The switch is solenoid operated. It comes with the buss bars on either the left or right hand sides so that switches connected in parallel on a single phase can be nested together. Having the switches close together makes the current divide more equal between switches connected in parallel. This switch contains one form A (normally open) and one form B (normally closed) auxiliary contact. A control for operating this switch is shown on page 13. The repair parts except for the modules are the same as for the 34 kV switch shown on page 48.

1. The terminal-to-terminal BIL is not established by a visible open gap and therefore the switch cannot be used to establish safety clearance for personnel.
2. When switches are used for capacitor bank switching, in-rush current levels need to be taken into consideration. Using reactors to reduce in-rush current reduces restrike probability. In back-to-back capacitor switching applications peak currents should be limited by reactors to a switch's high frequency inrush current rating. Excessive contact welding will occur, and operating performance negatively impacted if the in-rush currents are not limited below the switch ratings.
3. Switching a harmonic filter requires special considerations. Consult the factory about these applications.
4. For capacitor bank switching only, this switch is limited to being used on solidly grounded systems and solidly grounded capacitor banks with currents of less than 200 amperes.
5. When switches are used in parallel, the continuous current rating is reduced to 500 amperes to account for unequal current distribution between switches.

## Resistor Module

The 80 Ohm resistor module is used on resistor insertion switches for reducing in-rush currents. The resistor module contains eight $10 \mathrm{Ohm}, 10 \mathrm{kV}$ resistor elements. These resistor elements have aluminum contact surfaces to reduce corrosion and the resulting increase in resistance.

The module is supplied with an arc horn to protect it from over voltages in the event the in-rush current is so large that the withstand voltage was exceeded.

## 30 Microhenry Reactor

The 30 microhenry reactor is used to limit in-rush current when switching back-to-back (two or more capacitor banks installed in parallel on the same bus) capacitor banks. It is designed to be installed in place of the buss bar on the 34 kV switch shown on page 6 .

## Controls

## Capacitor Bank Switch Controls

The capacitor switch controls shown on these pages are different from other controls commonly used to operate Joslyn ${ }^{\mathrm{TM}}$ switches. First, they have extremely low power demands. Second, the control is very precise in timing switch contact opening and closing. Third, the controls are connected to the switches with cables having connectors on both ends to significantly improve installation time and eliminate the potential for wiring errors during installation.

The power demand is low because both the single and multiple switch controls are powered by switching power supplies with either 10,25 , or 60 watts. At these low power levels, the peak current demand is easily under 3 amperes and the maintenance charging current is minimal. Since the power demand is so low, voltage drops in long runs of wire to the control are eliminated along with any operating performance issues. The controls can accept $48 \mathrm{VDC}, 120 \mathrm{VAC}, 125 \mathrm{VDC}$, or 220 VAC inputs.

These controls are very precise in controlling switching time because the basic electronic circuitry used in all the controls was designed for closing switches at zero voltage. The precision is achieved both by electronic switching and having a closely regulated voltage on the stored energy capacitors. The zero voltage close switching feature is optional on three switch controls-

The controls are easy to diagnosis and repair. They are a modular assembly of circuit boards, wiring harnesses, and cables all of which can be quickly unplugged and replaced. This enables a person who is not familiar with the details of the circuitry and operation of the control to quickly isolate and determine what components are not working properly by substituting whole assemblies.

## Universal Single Switch Control

This control is called the universal control because it has field selectable options which permit it to be used in several different applications. The universal control can be used with 15 kV or 34 kV single switches. The control can be powered from either 120 VAC or 125 VDC. The trip and close command voltage can be either 120 VAC or 125 VDC . It also has an opto-isolated trip and close inputs which can be used to precisely time the closing of the switch.

The control has four energy storage capacitors but as delivered only two are connected. Switches with a single close or trip solenoid only require two capacitors. Switches with two close and two trip solenoids require four capacitors.

*Single Solenoid Switches only

# Boost Box Control for Three Pole Solenoid Operated Switches 

The Boost Box Control is designed to assure adequate power for reliable operations of solenoid operated switches involving only a single switch mechanism. Some substation layouts have long distances between the switch and the 120 VAC station transformer or 125 VDC battery bank. The line impedance combined with high current demand may result in an excessive voltage drop to the switch. If that occurs, the switch may operate too slowly or fail to operate.

A boost box is a practical and simple way to offset the undesired voltage drop. The boost box contains energy storage capacitors and is inserted in series with the existing switch pendant cable going from the control to the switch. The capacitors in the boost box then supply power to operate the switch. Another option is to replace the older control with a new Vesco control with stored energy.

## Multiple Switch Capacitor Bank Controls

Two Switch Zero Voltage Control

The two-switch control shown to the left is for switching unground neutral capacitor banks at zero voltage using the two-pole switch along with one single pole transverse switch as shown on page 16 .

This control is calibrated using Vesco calibration test kit part No. 1004054G1. During calibration, test leads are connected to the de-energized switch pole high voltage terminal pads to measure the switch timing. A laptop computer with a special program is connected to the control and is used to measure and set the switch timing.

## Three Switch Control

The three-switch control shown can operate a three-phase set of any single pole solenoid operated switch in this catalog except the VES-U switch. It can be ordered with either zero voltage close logic or as a regular control depending on the firmware installed. The three switches will achieve simultaneous contact closure within 2 milliseconds with minimal adjustment effort. The use of this control will substantially reduce the effort required to adjust switches for simultaneous operation when operated on 125 VDC .

## VES-U Capacitor Bank Control

The three-switch control can operate a three-phase set of VES-U poles shown on page 15. It can be ordered for either a zero voltage closing logic or as a regular control depending on the firmware installed. The three switches will achieve near simultaneous contact closure within 2 milliseconds with minimal adjustment effort. The use of this control will substantially reduce the effort required to adjust switches for simultaneous operation when operated on 125 VDC .

## Wind Farm Switch Control

This wind farm control is used for dynamic VAR compensation at wind farm applications. This control can operate three poles of any single pole solenoid operated switch in this catalog except the VES-U switch. The control can switch the poles with precision independently of each other at a frequency of every fifteen seconds. The control is powered by 125 VDC and requires a 5 kW power source with $31 / 2 \%$ maximum impedance.

This control's interface is designed to mate with Vizimax SynchroTeq ${ }^{\text {TM }}$ control module.

# Arc Furnace Control for 15kV Single -Mechanism Switches (15MVA and below) 

This control is for arc furnaces that are operated by one 15 kV 600 A three-pole switch. It is a stored energy control with a fast-charging circuit to enable frequent operation of the furnace switch.

The use of this control prevents problems caused by an inadequate current source to operate the control.

| Control Voltage | Control Part No. |
| :---: | :---: |

## Important Application Note

The fault interrupting rating of the Vesco arc furnace switch is $4,000 \mathrm{~A}$. On small transformers, the normal switch currents are less than 600 amperes, and the available short circuit current may be less than the vacuum switch $4,000 \mathrm{~A}$ rating. In this case, the switch can be used for overcurrent protection in conjunction with an overcurrent relay. If the available short circuit current is over 4000 A , and the switch is open in an attempt to clear the fault, significant damage can occur to the switch and the switch may not clear the fault. In this scenario, using another device for overcurrent protection is required.

Another precaution is to install overcurrent relay as part of the control scheme. The intelligence in these relays can recognize whether a fault current is within the capability of the switch. If the current is too large, the relay prevents the vacuum switch from opening and allows an upstream protection device to clear the fault.

## Arc Furnace Control for 15 to 46kV Multiple -Mechanism Switches (Greater than 15MVA)

This control is for an arc furnace with 3,000 amperes primary current at 15 kV or 1500 amperes at $34 / 46 \mathrm{kV}$. It can operate nine switches total which equates to three switch mechanisms per phase. It is a direct
 replacement for a Joslyn ${ }^{\mathrm{TM}}$ arc furnace control. The control shown is representative of a whole range of controls available which are capable of operating from three to eighteen switch mechanisms. The control is modular for easy diagnosis and repair.

This control can minimize transient in-rush current either with resistor insertion switches or synchronous closing logic in which the switches are programmed to close at the peak voltage point on system's voltage sine wave.

The control is operated by an Allen Bradley ${ }^{\text {TM }}$ PLC. The PLC has diagnostics built into its program. The control can detect a switch mechanical malfunction and initiate an emergency trip to prevent single phasing of the furnace transformer. Single phase power on a furnace transformer is a frequent cause of arrestors failures.

The PLC has an ethernet connection for remote monitoring with a PanelView ${ }^{\text {TM }}$ monitor. The PanelView ${ }^{\mathrm{TM}}$ monitor graphically displays individual switch open or closed status and maintains a date and time stamped log of any potential switch malfunctions which resulted in the control being reset.

## Induction Furnace Resistor Insertion Switch Control

This control operates two 15 kV 600 A three pole switches in a resistor insertion switch arrangement for transient in-rush control. The control first closes one switch through 80 Ohm resistor modules. One hundred milliseconds later the control closes a second switch bypassing the resistors.

## Arc Furnace Control for VES-U or Joslyn ${ }^{\text {TM }}$ VBU

The control operates Vesco VES-U switches and is a direct replacement for a Joslyn ${ }^{\text {TM }}$ VBU control. VESU switches shown on page 15 can be used at primary voltages of 69 kV to 145 kV . The control shown operates two poles per phase, but it can be expanded to operating up to five poles per phase.

The control is modular in design for easy diagnosis and repair. A person who does not know all the details of the control can diagnose problems by substitution. The control is connected to the switch by a cable with a connector on both ends to reduce wiring at installation. An adaptor kit is provided to install a receptacle on each VES-U or VBU pole.

This control can minimize transient in-rush current either with a resistor insertion switch or by synchronous closing logic in which the switches are programmed to close at the peak voltage point on system's voltage sine wave.

The control operates on stored energy for both closing and opening. It is operated by an Allen Bradley ${ }^{\text {TM }}$ PLC which has diagnostics built into its program. The control can detect a switch mechanical malfunction and initiate an emergency trip to prevent single phasing of the furnace transformer. Single phase power on a furnace transformer is a frequent cause of arrestors failures.

The PLC has an ethernet connection for remote monitoring with a PanelView ${ }^{\text {TM }}$ monitor. The PanelView monitor graphically displays individual switch open or closed status and maintains a date and time stamped $\log$ of switch malfunctions.

## Calibration Cable \& Software Set

The Calibration cable and software set are used to calibrate Vesco controls for zero voltage closing (for capacitor bank switching) or for peak voltage closing (transformer switching).

## VESCO

The VES-U mechanism is designed to provide a very long life and incorporates improvements over the similar Joslyn ${ }^{\mathrm{TM}}$ mechanism. Improvements have been made to many parts, such as the operating cams, the contact blocks, bearings, and various other components. These changes enabled the mechanism to achieve over 75,000 operations. Those changes, along with vacuum module improvements, result in an extremely reliable switch system.

## Counters \& Position Indicators

Vesco switches are manufactured with a six-digit operations counter located within the position indication assembly. There have been varying types of counters used in Joslyn type switches. Counters can be attached to the manual operating handle cover, internal to the switch, and an externally visible six-digit version. The five-digit and six-digit counters are shown below. The five digit and handle cover counters are not available.

During switch overhauls old switches without externally visible counters are modified to use the new externally visible six-digit counter with a position indicator. This upgrade makes it easier to track switch operations for purposes of scheduling maintenance. The modification can only be done in the factory because it requires welding and re-machining of the switch mechanism casting. The window for the new counter and position indicator is sometimes located where the existing name plate is located. In this instance, Vesco replaces the old name plate with a new name plate having the old serial number.

## Replacement Parts for Joslyn ${ }^{\text {TM }}$ Controls

The two Joslyn ${ }^{\mathrm{TM}}$ circuit boards shown below are used by Joslyn in both their zero-voltage control for capacitor banks and also their Point-of-Wave ${ }^{\mathrm{TM}}$ controls for arc furnaces. Shown opposite the Joslyn boards are the Vesco plug-for-plug compatible replacement board. The SCR boards are functionally equivalent except that the Vesco board has transient suppression components on the board whereas the Joslyn board requires that surge suppression be installed at the terminal connections during the board installation.

While functionally equivalent, the timing boards are designed using different concepts. The Joslyn timing board has analog circuitry to control the timing. The timing adjustments are made by turning three trip potentiometers on the board. The Vesco timing board has digital circuitry. The timing is controlled with a crystal oscillator, and the switch timing can be digitally set in increments of 25 microseconds. The Vesco digital board has an RS232 connection which can be connected to a computer and used to measure and set switch timing.
